

# Guidance for Installers: How to Complete an SOWDG Work Sheet Appendix 7 of the Guide

This fact sheet is intended to aid contractors in completing the design worksheet for a Type II mound onsite wastewater treatment and disposal system using table A.15. Please note that the most current Saskatchewan Onsite Wastewater Disposal Guide and all relevant legislation should be reviewed for further reference and to ensure that all necessary actions are completed. When designing a system, the information contained within the guide is considered a minimum. Some information within this sheet may result in a design that is greater than the suggested minimums described.

In Appendix 7 of the Saskatchewan Onsite Wastewater Disposal Guide, a worksheet is available to help contractors size a Type II mound. This fact sheet provides further guidance on completing the worksheet. For this example, the residence for which the Type II mound is designed for is a three bedroom home with an unfinished basement (owner plans on finishing with an additional room) and a master suite with a 67 gallon (300 litre) jet tub. Soil testing has determined that the soil is a granular sandy clay. There is more than 4 feet of material to any restrictive layer and the site is flat.

Note that throughout the fact sheet, the boxed in areas are excerpts from the worksheet contained in Appendix 7 of the Saskatchewan Onsite Wastewater Disposal Guide.

**Responsibility for interpretation of the content of this fact sheet rests with the user. Information in this fact sheet is provided solely for the users information and, while thought to be accurate, is provided strictly as is and without warranty of any kind, either express or implied. The Province of Saskatchewan hereby disclaims any liability or responsibility for any injury or damage resulting from the use, directly or indirectly, of the information contained herein.**

# 1

## Determine Sewage Flows

The facility to be served should be examined. For residential systems, the maximum sewage volume per day is estimated based on the number of bedrooms in the home. It is the responsibility of the installer to ensure that the estimate of bedrooms is reasonable for the home. For example, homeowners should be questioned regarding plans for unfinished basements in new homes. Other water using habits such as large whirlpool baths, multi-head showers, and hosting large parties should also be considered when selecting the maximum and average day sewage flows.

In general, a typical home should be considered to generate a maximum sewage 340 litres (75 igtal) per person per day and an average flow of 255 litres (56 igtal) per person per day. For homes larger than two bedrooms, 1.5 people are considered to be present for each bedroom. Exceptional water uses should be considered above these values. Appendix 2 can be used to estimate the smallest sewage flows that can be used for a number of different types of facilities.

The first step in sizing the example sewage treatment field (in this example a type II mound) is to determine the volume of sewage that can be expected to be generated on the worst day over the lifespan of the system. For this example, the expected volume of sewage could be considered to be 4 bedrooms times 1.5 people times 75 imperial gallons plus 67 gallons, which equals 517 gallons per day. Four bedrooms were selected because the owner plans on finishing the basement to include a fourth bedroom. The value of 67 imperial gallons was added to account for the presence of a large jet tub as a jet tub is not considered to be part of the typical residence water usage of 1.5 people per bedroom.

### Determine the expected volume of sewage per day.

**Note:** Use Appendix 2 as a guide to determine expected volume of sewage per day.

Provide allowance for additional load factors.

Assure that the sewage strength does not exceed the requirements of Residential Strength Sewage.

### Expected Volume of Sewage per Day

517 gal/day M1

# 2

## Determine Area of Sand Layer

The area of the sand layer is determined by dividing the expected volume by the loading rate allowable on the sand layer.

### Calculate the treatment area of the sand layer:

Expected Volume of Sewage per Day

517 gallons

From M1 this worksheet

Sand Layer Effluent Loading Rate

1 gal / ft<sup>2</sup> (or 50 L / m<sup>2</sup>) per day =

Treatment Area Required for Sand Layer

517 ft<sup>2</sup> M2

# 3

## Determine the Minimum Allowable Sand Layer area

In every case, the sand layer is not allowed to be less than 400 ft<sup>2</sup> so the final area of the sand layer is the greater of that calculated in step 2 (517 ft<sup>2</sup>) and 400 ft<sup>2</sup>.

Determine the minimum allowable sand layer area:

Minimum Sand Layer	Area of Sand Layer for Treatment	Area of Sand Layer	
<u>400 ft<sup>2</sup></u>	<u>517 ft<sup>2</sup></u>	<u>517 ft<sup>2</sup></u>	<b>M3</b>
<i>The minimum area of the sand layer is 37.16 m<sup>2</sup> (400 ft<sup>2</sup>)</i>	<i>From M2, this worksheet</i>	<i>The greater of 37.16 m<sup>2</sup> (400 ft<sup>2</sup>) or M2</i>	

# 4

## Calculate the Length of the Sand Layer

Now that the area of the sand layer is known, the exact dimensions should be determined. The width of the sand layer can be selected up to a maximum of 10 ft, however, additional guidance can be obtained by understanding and using Table A.15. For the purposes of the example, we will select a width of 3 feet.

Calculate the length of the sand layer:

Area of Sand Layer	Width of Sand Layer	Length of Sand Layer	
<u>517 ft<sup>2</sup></u>	<u>3 ft</u>	<u>172 ft</u>	<b>M4</b>
<b>M4a</b> <i>From M3, this worksheet</i>	<b>M4b</b> <i>Select a width to a maximum of 3 m (10 ft)</i>		

# 5

## Determine the (Design) Soil Effluent Loading Rate

One can select the soil effluent loading rate in a number of ways. If the Health Region allows, a percolation test may be used. In which case, the loading rate can be selected from the fourth column of Appendix 1. A more detailed approach is to complete soils testing and select the loading rate based on the listing in Appendix 15. However, as the soil type in this example is Sandy Clay, the listing gives “not suitable without further testing”. Therefore Table A.15, which is based upon both the texture and the structure of the soils, should be used. Determining the structure of the soil is not covered in this fact sheet, but the example gives the structure as granular. Looking at table A.15, “SC” stands for sandy clay, and GR stands for Granular. In the BOD >30 column (4th column from the left), a loading rate of 0.14 imperial gallons per square foot is given. This loading rate describes the allowable application rate of the sewage to the underlying soils not to the sand layer.

Determine the (design) soil effluent loading rate:

Soil Effluent Loading Rate

Note: Effluent loading rate can be determined from soil texture classification or from percolation test results according to Appendix 8. Appendix 1 provides the effluent loading rates from soils between 5 and 120 min/inch perc rates.

0.14 gal/ft<sup>2</sup> per day **M5**

## 6 Calculate the Preliminary Infiltration Area of the Soil

Using the expected sewage volume from Step 1 and dividing by the loading rate determined in Step 5, the infiltration area of native soil is determined to be 3693 ft<sup>2</sup>.

Calculate the preliminary infiltration area of soil before area reduction factors:

Expected Volume of  
Sewage per Day

Soil Effluent  
Loading Rate

Preliminary  
Infiltration Area

**M6**

517 gallons ÷ 0.14 gal/ft<sup>2</sup> per day = 3693 ft<sup>2</sup>

*From M1, this worksheet*

*From M5, this worksheet*

*(Required for Soil. Before  
Reduction Factors.)*

## 7 Apply Allowed Soil Size Reduction Factors

As this system being constructed is a mound system, a 30% reduction of size is allowed. This reduction is based on the enhanced treatment capacity of the sand layer when compared to a standard field system.

Calculate the required infiltration area including allowed area reduction factors:

Infiltration Area  
Required for Soil

Reduced Area  
Factor

Required  
Infiltration Area

**M7**

3693 ft<sup>2</sup>      0.7      2585ft<sup>2</sup>

*(Before Reduction Factors.)  
From M6 this worksheet*

*A reduction of up to 30%  
(1-0.70) can be applied to  
Type II Mounds*

*(Including reduction  
factors)*

# 8

## Calculate the Required Width of the Infiltration Area

The length of the mound is the same as the length determined for the sand layer and in this example the length of the sand layer was determined to be 172 ft. This is therefore the length of the overall mound and the width can be calculated by dividing the known area by the length.

Calculate the required width of the infiltration area:

<b>Required Infiltration Area</b>		<b>Length of Sand Layer</b>		<b>Width of Required Infiltration Area</b>	
<u>2585ft<sup>2</sup></u>	÷	<u>172 ft</u>	=	<u>15 ft</u>	<b>M8</b>
(Including Reduction Factors.) From <b>M7</b> this worksheet		From <b>M4</b> this worksheet			

# 9

## Determine the Slope Criteria

In this example the slope was given as 0%. However, if the slope is greater than 1%, the overall size of the mound may be determined by either a) the need to ensure that the slopes are not excessively steep, or b) the need to cover the whole required infiltration area. In this example, if the mound area does not cover 2585 ft<sup>2</sup>, break-out of sewage onto the surface of the ground is very likely.

Determine the slope criteria of the installation site:

If the slope of the installation site exceeds 1%. proceed to Step 12.  
If the slope is 1% or less, proceed to Step 10

**Slope of the  
installation site**

0%

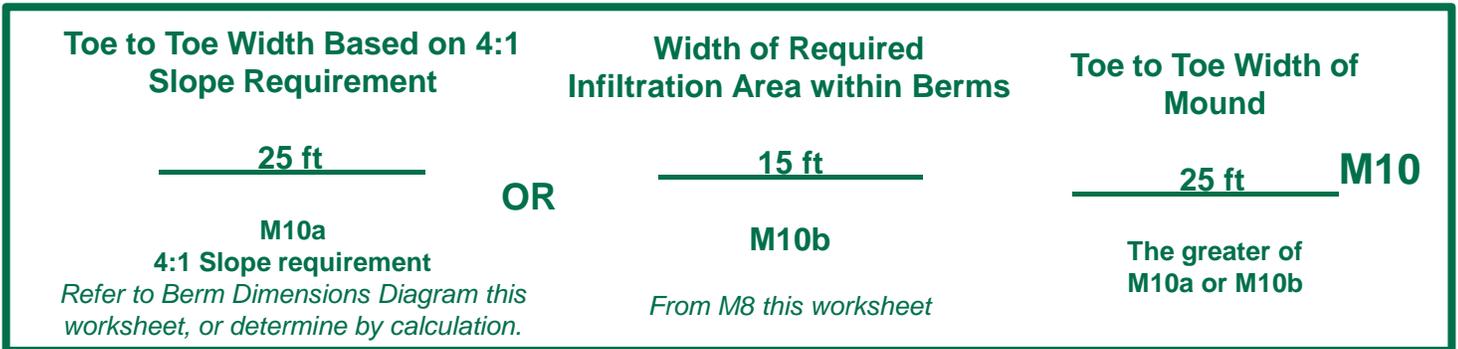

**M9**

**Note:** the following calculations apply **ONLY** to the minimum height configuration of a mound. If it is necessary to raise the sand layer, (for example to provide clearance to the water table) the following calculations are **NOT** adequate for the design.

For Slopes of 1% or less, go to Step 10 - slopes greater than 1%, go to Step 12.

# 10 Determine the Toe to Toe Width of the Mound

Based on a maximum of 4 horizontal to 1 vertical slopes, and a typical height of 33 inches (3 inches of topsoil over 6 inches of fill over 12 inches of gravel/chambers over 12 inches of sand) the minimum horizontal distance of the berm from the edge of the sand layer to ground surface is 33" times 4, which equals 132" or 11 ft. Therefore the total toe to toe width based only on geometry is 11 feet on each side plus the width of the sand layer (3 ft), which, in this example equals 11 ft + 3 ft + 11 ft or 25 ft. In step 8, we calculated the width of the infiltration area that needed to be covered as 15 ft. To select the total width, the maximum of the two numbers (one is determined to ensure that the side slopes are not too steep and the other is to ensure that sufficient native soil is covered to allow the wastewater to infiltrate to below ground). In the example, this is 25 ft.

**After completing Step 10, proceed to Step 16.**

# 11 Remember:

**For Slopes of 1% or less, Step 10, then 16**  
**For Slopes greater than 1%, Steps 12-15, then 16**

# 12 Determine the Width of the Sand Layer Plus the Downslope Berm

**For slopes greater than 1%, use steps 12-15**

For the purposes of demonstration, we will assume that the example had a slope of 3%. Steps 12 to 15 (only) will be based on this slope. In this case, we should use a diagram to determine the geometrical minimum size of the mound from toe to toe (based on ensuring that the slopes are not too steep). By looking at the diagram at the end of Appendix 7 of the Onsite Wastewater Disposal Guide, select the downslope distance. In this example, it would be 13 ft – 10 in.

In the case that the mound is located on a slope, only the downslope toe of the berm is considered to be effective for wastewater infiltration. This is because water will not run uphill from the sand layer to infiltrate through the upslope covered area. In this calculation, you can see that the geometry of the mound is the limiting factor. Even though, this example demonstrates that geometry is the limiting factor, it is important to complete this step as often the amount of area required for infiltration into the native soil is limiting.

### Determine the width of the sand layer plus downslope berm:

The width of the mound is based on the **greater of**:

- the width as determined by the 4:1 slope requirement, **or**
- the width required to provide adequate infiltration area.

**Downslope Berm Width Based on 4:1 Slope Requirement Plus Width of Sand Layer**

13 feet 10 inches

**M12a**

Refer to Berm Dimensions Diagram this worksheet

**+**

**Sand Layer Width**  
3 feet

**M12b**

from M4b Worksheet

16 feet 10 inches

**M12c**

4:1 Slope Requirement

OR

**Width Required Infiltration Area under Sand Layer and Downslope Berm**

15 feet

**M12d**

From M8 this worksheet

**Width of Sand Layer and Downslope Berm**

16 feet 10 inches

**M12**

The greater of M12c or M12d

# 13

## Determine the Width of the Upslope

From the diagram, select the appropriate upslope distance (9 feet 10 inches for the example).

Determine the Width of the upslope berm:

**Width of Upslope Berm**

**Width Based on 4:1 Slope Requirement**

Refer to Berm Dimensions Diagram this worksheet, or determine by calculation.

9 feet 10 inches

**M13**

# 14

## Determine the Toe to Toe Width of the Mound - Slopes >1%

The toe to toe width of the mound includes both the width calculated in Step 12 and Step 13. In the example where the slope is 3%, the total width is 26 ft 8 inches.

### Determine the Toe to Toe Width of the Mound:

Width of Sand Layer  
and Downslope Berm

16 feet 10 inches

*From M12 this workbook*

+

Width of Upslope Berm

9 feet 10 inches

*From M13 this workbook*

=

Toe to Toe Width of  
Mound

26 feet 8 inches

**M10**

# 15

## Proceed to Step 16

For Slopes Greater than 1%, Steps 12-15 should be completed

# 16

## Summarize the Information

Based on the original example of a flat site.

Width of Sand Layer

*(from M4b this worksheet)*

3 feet

Length of Sand layer

*(from M4 this worksheet)*

172 feet

Slope of Installation Site

*(from M9 this worksheet)*

0%

Toe to Toe Width of Mound

*(from M10 or M14 this worksheet)*

25 feet

# 17

## Complete the Berm Diagram

Fill out the appropriate boxes on the first page of appendix 7

Complete the berm diagram dimensions on first page.

Fill in the appropriate diagram on the first page with the numbers calculated in this worksheet.

# 18

## Confirm Design Complies with the Guide

Lastly, it is the responsibility of the designer and installer to ensure that all requirements in the guide and from the health region are complied with.

Confirm the design complies with the guide.

This worksheet does NOT consider all the requirements of the Guide. Please work safely and follow safe practices near trenches and open excavations.
